

## Time-fractional stochastic conservation laws

(joint work with Martin Scholtes)

We consider time-fractional scalar conservation laws of the form

$$dg_{1-\alpha} * (u - u_0) + \operatorname{div} f(u)dt = I^{1-\beta}hdW,$$

where  $g_{1-\alpha}(t) = \frac{t^{-\alpha}}{\Gamma(1-\alpha)}$  ( $\alpha \in (0, 1)$ ), i.e.,

$$\partial_t g_{1-\alpha} * (u - u_0) = \partial_t^\alpha (u - u_0)$$

is the fractional time-derivative in the sense of Riemann-Liouville,

$f : \mathbb{R} \rightarrow \mathbb{R}^N$  is a smooth function, and

$I^{1-\beta}$  is the fractional integral of order  $1 - \beta$  in the sense of Riemann-Liouville ( $\beta = 1$  corresponds to the classical additive stochastic noise  $hdW$  with a given function  $h$  and  $W = (W(t), \mathcal{F}_t, 0 \leq t \leq T)$  one-dimensional Brownian motion on a classical Wiener space).

Under certain assumptions on  $\alpha$  and  $\beta$  we prove existence and uniqueness of stochastic entropy solutions for arbitrary  $L^2$ -initial data.

An interesting open question is whether it is possible to generalize these results to the case of a multiplicative stochastic noise. The main difficulty is that an Itô type formula is not known to exist in the time-fractional derivative case.
